

Test Specific Guidelines

Expanded Carrier Screening Panels

MOL.TS.165.A
v1.0.2023

Introduction

Expanded carrier screening panels are addressed by this guideline.

Procedures Addressed

The inclusion of any procedure code in this table is provided for informational purposes and is not a guarantee of coverage nor an indication that prior authorization is required.

<u>Procedures addressed by this guideline</u>	<u>Procedure codes</u>
<u>Ashkenazi Jewish Genetic Disorders Sequencing</u>	<u>81412</u>

<u>SMPD1 Targeted Mutation Analysis</u>	<u>81330</u>

What Are Expanded Carrier Screening Panels?

Definition

Expanded carrier screening panels, also known as multiplex carrier screening panels, are designed to identify carrier status or predict risk for multiple genetic diseases in a single test. It is typically offered to individuals planning a pregnancy or currently pregnant.

Prevalence

The genetic diseases that are tested for range in severity from lethal in infancy to so mild an affected individual may never develop symptoms. Some conditions are quite common, especially in certain ethnic groups, while others are rare.

It is generally believed that all people carry several recessive gene mutations. An estimated 1 in 580 births has an autosomal recessive condition and 1 in 2000 have an X-linked condition.¹

Inheritance

Expanded carrier screening panels may include autosomal recessive and X-linked conditions.

Autosomal recessive inheritance

In autosomal recessive inheritance, individuals have 2 copies of the gene and an individual typically inherits a gene mutation from both parents. Usually only siblings are at risk for also being affected. Males and females are equally affected. Individuals who inherit only one mutation are called carriers. Carriers do not typically show symptoms of the disease, but have a 50% chance, with each pregnancy, of passing on the mutation to their children. If both parents are carriers of a mutation, the risk for each pregnancy to be affected is 1 in 4, or 25%.

X-Linked Inheritance

In X-linked inheritance, the mutation is carried on the X chromosome. Females have two X chromosomes, and males have one. Males typically have more severe symptoms than females. A female with a mutation has a 50% chance to pass that mutation to her children. A male with a mutation cannot pass the mutation to any sons, but will pass it to all daughters. A process called X-inactivation in females results in random inactivation of expression of one X-chromosome in each cell of the body. For females with one mutation, the percentage and distribution of cells with expression of the X chromosome carrying the mutation can influence the degree of severity.

Common Uses

Expanded carrier screening is most commonly done for reproductive planning, to identify couples at risk for having a child with a recessive inherited disorder. In most cases, couples who have a child with a recessive inherited disorder have no family history of that disorder or any other risk factors.

Carrier screening for a specific disorder may be indicated when there is a positive family history, when a reproductive partner is a carrier of or affected with a recessive disorder, or when there is a known increased risk based on ethnicity or other factors.

Test Information

Introduction

Expanded carrier screening panels determine carrier status for numerous genetic conditions simultaneously for the purposes of reproductive planning.

Expanded Carrier Screening Panels

Several expanded carrier screening panels are available. Each test has a unique set of diseases included in novel and proprietary genetic testing platforms. The number of mutations tested varies considerably by condition, ranging from a single mutation for rare conditions to over 100 mutations for cystic fibrosis. Complete testing information, including a list of all conditions screened, can be found at a laboratory's website.

Guidelines and Evidence

Introduction

This section includes relevant guidelines and evidence pertaining to expanded carrier screening.

American College of Obstetrics and Gynecology

The American College of Obstetrics and Gynecology (ACOG, 2017)² published a committee opinion that stated the following regarding Expanded Carrier Screening:

“Ethnic-specific, panethnic, and expanded carrier screening are acceptable strategies for prepregnancy and prenatal carrier screening. Each obstetrician–gynecologist or other health care provider or practice should establish a standard approach that is consistently offered to and discussed with each patient, ideally before pregnancy. After counseling, a patient may decline any or all carrier screening.” “Given the multitude of conditions that can be included in expanded carrier screening panels, the disorders selected for inclusion should meet several of the following consensus-determined criteria: have a carrier frequency of 1 in 100 or greater, have a well-defined phenotype, have a detrimental effect on quality of life, cause cognitive or physical impairment, require surgical or medical intervention, or have an onset early in life. Additionally, screened conditions should be able to be diagnosed prenatally and may afford opportunities for antenatal intervention to improve perinatal outcomes, changes to delivery management to optimize newborn and infant outcomes, and education of the parents about special care needs after birth.”

- “Carrier screening panels should not include conditions primarily associated with a disease of adult onset.”

American College of Medical Genetics and Genomics

The American College of Medical Genetics and Genomics (ACMG, 2021) released an educational practice resource on carrier screening.³ This consensus statement asserted that general population carrier screening should be ethnicity and family history agnostic. To accomplish this, screening all individuals in the prenatal/preconception period for autosomal recessive and X-linked conditions with a carrier frequency of $>1/200$ was suggested. ACMG generated a list of 113 genes meeting these criteria.

Concerns with Large Panels

Although the number of large panels being offered by laboratories is increasing, most of the included tests are not indicated for each person being tested.

Issues with expanded carrier screening include:

Many included tests have not been recommended for population-based carrier screening and should therefore only be performed when there is a specific known increased risk, such as a family history of the condition.

Some conditions included in expanded carrier screens are exceedingly rare except in certain ethnicities, or the carrier frequency in the general population may not be known. Therefore, the residual risk for an individual after a negative expanded carrier screen may not be provided by the laboratory.³

Mutation analysis may not be the preferred initial screening test for some conditions. For example, a CBC with RBC indices is the initial screening test for beta-thalassemia followed by hemoglobin analysis for individuals with microcytic anemia.^{4,5} Measuring hexosaminidase A activity may be preferable to mutation analysis for Tay-Sachs carrier screening, especially in non-Jewish populations.⁵

Some expanded carrier screens include testing for conditions that are relatively mild, treatable, or have onset in adulthood.

- Depending on ethnicity, current expanded carrier screening panels are expected to identify up to 40% of people tested as carriers of a recessive gene mutation. Therefore, if this screening is routinely offered, many patients will require counseling for a positive result, and partner testing must be offered. The most complete partner testing is often by full gene sequencing. Availability of partner testing, cost, turnaround time, and the possibility of identifying a variant of unknown significance by sequencing make this a complex clinical scenario to manage in the routine reproductive setting.

Criteria

Introduction

Requests for expanded carrier screening panels are reviewed using these criteria.

Individually Billed Gene Tests

Individual gene tests included in expanded carrier screening panels that will be separately billed should be evaluated based on the medical necessity criteria for each gene test.

Any gene tests that are separately billed and do not meet medical necessity criteria are not a reimbursable service. It will be at the laboratory, provider, and patient's discretion to determine if a multi-gene panel remains the preferred testing option, recognizing that only a portion of the panel may be reimbursed by insurance.

Single Panel Code Billed

Panel will be billed with a single procedure code, 81443, to represent all genes being sequenced.

No single gene components of the panel have been performed and reimbursed previously, or billed separately on the same date of service, AND

- **Medical necessity must be established for full gene sequencing of at least two conditions included in the panel. This does not include:**

targeted mutation testing (i.e. cystic fibrosis carrier testing performed by a panel of mutations, or known familial mutation testing), or

molecular methodologies other than sequencing (i.e. fragile X testing; deletion/duplication analysis of any gene by MLPA or similar platform), or

- **non-molecular methodologies (i.e. hemoglobin electrophoresis for hemoglobinopathies)**

Billing and Reimbursement Considerations

The following conditions should not be billed as part of 81443 and should not count toward the requirement of two conditions meeting medical necessity requirements:

Spinal muscular atrophy carrier testing should be billed separately using 81329

- **Fragile X testing should be billed separately using 81243**

Carrier testing performed due to the sole indication of Ashkenazi Jewish ancestry will be redirected to 81412.

Coverage Guidance

This table describes coverage guidance around the most commonly performed carrier screening tests. It also includes the test types addressed by population-based carrier screening guidelines. When the test is not addressed in this table, refer to the general guideline: Genetic Testing for Carrier Status. For these

additional tests to be medically necessary, there will generally need to be a specific known increased risk for that condition such as a known family history or a reproductive partner who is known to be a carrier of or affected with the condition.
